ABSTRACT

Future and even current European farmers are experiencing that the managerial tasks for arable farming are shifting to a new paradigm, requiring increased attention to economic viability and the interaction with the surroundings. To this end, an integration of information systems is needed to advise managers of formal instructions, recommended guidelines and documentation requirements for various decision making processes. In the EU funded project FutureFarm, a new model and prototype of a new Farm Information Management System (FMIS) which meets these changing requirements will be developed. The aim of the work presented in this paper is to define and analyse the system boundaries and relevant decision processes for such a novel FMIS as a prerequisite for a dedicated information modelling.

The boundaries and scope of the system are described in terms of actors and functionalities, where actors are entities interfacing with the system (e.g. managers, software, databases). In order to analyse the complex and soft systems situations of how to develop an effective FMIS, which effectively meets farmers' changing needs a conceptual model was developed based on soft systems methodology (SSM) and based on information derived from four pilot farms representing diverse conditions across the EU that are partners of the FutureFarm project. The system components were depicted as part of rich pictures and linked to the subsequent derived conceptual model of the overall system as an outline for the development of the specific FMIS requirements. This research has shown the benefit of using dedicated system analysis methodologies as a preliminary step to the actual design of a novel farm management information system compared with other more rigid and activity oriented system analysis methods.

1. Introduction

The managerial tasks in agriculture are currently shifting to a new paradigm, requiring more attention on the interaction with the surroundings, namely environmental impact, terms of delivery, and documentation of quality and growing conditions (e.g. Sigrimis et al., 1999; Dalgaard et al., 2006). Among other things, this managerial change is caused by external entities (government, public) applying increasing pressure on the agricultural sector to change production from a focus on quantity to an alternate focus on quality and sustainability (Halberg, 2001). This change has been enforced by provisions and restrictions in the use of production

input (e.g. fertilisers, agrochemicals) and with a change of emphasis for subsidies to an incentive for the farmer to engage in a sustainable production rather than based solely on production. In general, this change of conditions for the managerial tasks on the farm has necessitated the introduction of more advanced activities monitoring systems and information systems to secure compliance with the restrictions and standards in terms of specific production guidelines, provisions for environmental compliance and management standards as prerequisites for subsidies. Until now, farmers most often have dealt with this increased managerial load by trying to handle manual a mass of information in order to make correct decisions. The increasing use of computers and the dramatic increase in the use of the internet have to some degree improved and eased the task of handling and processing of internal information as well as acquiring external information. However, the acquisition and analysis of information still proves a demanding task, since information

* Corresponding author. Tel.: +45 89991930.

E-mail address: claus.soerensen@agrsci.dk (C.G. Sørensen).

is produced from many sources and may be located over many sites and is not necessarily interrelated and collaborated. The potential of using these data will reach its full extent when suitable information systems are developed to achieve beneficial management practices (Blackmore et al., 2006). McCown (2002) argued that in designing an information system, the emphasis should be placed less on design and more on learning what the farmers do and how they act, and not only letting researchers design their own views of farm management decisions. Additionally, Alvarez and Nuthall (2006) while realizing that the technology in the farm office was not as extensive as they could expect, and while looking at the potential problems pointed out that software developers should understand the farmers and work closer with them and that the resulting systems should be adaptable to suit a range of farmer characteristics. Specific attempts to improve this situation have included the launch of “web-based collaborative information systems”, combining different information components (models, data, text, graphics) from different but collaborating sources (e.g. Jensen et al., 2001). However, such systems still have to be enhanced in terms of collaboration with automated acquisition of operational farm data and integration with the overall Farm Management Information System (FMIS).

Advances in precision agriculture, such as positioning systems and sensors for yield and machinery performance monitoring allows farmers to acquire vast amount of site-specific data which ultimately can be used to enhance decision making (Blackmore, 2000; Fountas et al., 2006). Currently, however, this automatically collected data or data by manual registration is not used due to data logistic problems, leaving a gap between the acquiring of such data and the efficient use of this in agricultural management decisions making (Atherton et al., 1999; Pedersen et al., 2004; Reichardt and Juergens, 2009). Costs of time spent managing the data in many cases outweigh the economical benefits of using the data and it seems that future use of wireless communication is gaining much of interest (Speckman and Munach, 2001; Jensen et al., 2007). In all, a refined and integrated solution to analyse and transform the acquired data is needed to improve decision making in the future (Fountas et al., 2005).

With the current transformation of the agricultural sector and the need for better analysis and transformation of the collected data additional demands on the precision and integration of the planning and control functions have occurred, requiring that the planning considers the dynamic interaction of machine, biological, and meteorological conditions (e.g. Kuhlman and Brodersen, 2001). This resembles the industrial adoption of computer-integrated manufacturing (CIM) and its embracing of customised production followed by dynamic operations planning and control of operations (Nagalingam and Grier, 2008). The industry has demonstrated how effective an integrated control of work operations can be, based on on-line measurements combined with database and decision support information (McCarthy, 1990; Riezebos et al., 2009). This is especially the case in terms of integrating information technology and information systems in supply chain activities (e.g. Gunasekaran and Ngai, 2004).

In this regard, it has been shown that the enhancement of FMIS is more influenced by common business factors and drivers than specific farming activities (Lewis, 1998). Plan generation and execution of farm operations must be linked with a system monitoring effects of actions, unexpected events and any new information that can contribute to a validation, refinement, or reconsideration of the plan or goal. Plans must be presented in a conditional way, such that supplementary knowledge from observations, databases, sensors and tests can be incorporated and integrated to revise the plan in the light of new information. This involves an extended use of modelling and simulation as opposed to providing a generalised optimal solution (Attonaty et al., 1999; Ohlmer et al., 1998).

A detailed structuring and formalisation of physical entities and the information which surrounds the planning and control of farm operations using efficient mobile working units in automated agricultural plant production systems is a decisive prerequisite for the development of comprehensive and effective ICT-system supporting the task management efforts. An increase in the adoption of new information technologies requires that the functional requirements surrounding the use of such technologies must be explicitly specified (Sørensen et al., 2007). By specifying in detail the information provided and the information required for the information handling processes, the design and functionalities of the individual information system components can be derived. That is the case both for on-board machinery information systems as well as for supporting service information systems. The information flows may be contextualised on different levels and in different details (e.g. Fountas et al., 2006; Sørensen et al., 2007; Nash et al., 2009a).

1.1. Concept of management information systems (MIS)

Management information systems (MIS) are an integral part of the overall management system in an purposeful organisation and form parts of tools such as enterprise resource planning (ERP) and overall information systems (IS). ERP is an industry notion for a wide set of management activities which support all essential business processes within the enterprise. The management systems support management activities on all levels as well as provide for the identification of key performance indicators (KPI's) (Folinas, 2007). Typically, ERP is directly integrated with information systems in the form of databases and will often include applications for the finance and human resources aspects of a business.

MIS differs from regular information systems because the primary objectives of these systems are to analyse other systems dealing with the operational activities in the organisation. In this way, MIS is a subset of the overall planning and control activities covering the application of humans, technologies, and procedures of the organisation. Within the field of scientific management, MIS is most often tailored to the automation or support of human decision making (O'Brien, 1999). Fig. 1 shows the conceptual decomposition of the different management systems in an organisation.

By following this conceptual framework and notation, a FMIS is defined as a planned system for the collecting, processing, storing and disseminating of data in the form of information needed to carry out the operations functions of the farm.

1.2. Diversity of European agriculture

The diversity among European agricultural holdings in terms of farm type, size, geography, cultural differences, etc. has a significant impact on the decision making process of the farmers (e.g. Ohlmer et al., 1998). By structuring the complexity of farms, regions, and technologies for information driven crop production, some indications have been derived which illustrate the issue of FMIS transferability within the EU. Likely issues for worldwide transferability may be extrapolated from this analysis.

The total agricultural area within EU-27 is about 183 million hectares – see Table 1. About 85% of the farm holdings have an area below 20 ha (Danish Agriculture, 2007). The farm area structure varies from an average at about 5 ha per farm holding in Greece to 79 ha on average in the Czech Republic. With the accession of Romania and Bulgaria into the European Union, the number of farm holdings has increased significantly due to numerous small farms in Romania. About 32% of the agricultural area is cultivated with cereals of which wheat is the most common crop. About 40% of the cereals are produced in France and Germany. Farming has been less

Fig. 1. Concept of management information systems (Sørensen et al., 2009).

intensive in many east European countries with reduced yields as a consequence – this may be seen in the two neighbouring countries Germany and Poland, where the difference in potato yield is significant.

Countries such as Denmark, besides crop production, focused on intensive animal production with a focus on pigs and dairy and related agricultural industries. The geographical and climatic differences determine that the cropping season, radiation and precipitation varies from the north to south. Crops such as olives, cotton and citrus, which are common in the Mediterranean countries, cannot be cultivated in the north, while for certain areas and crops it is possible to have several growing seasons during the same year.

Based on the outlined differences, it is inherent that new FMISs must be designed to accommodate the geographic and cultural differences among the European regions.

1.3. Objectives

The overall objective of this study was to create a basic outline and structure for a FMIS for planning and control of crop production by using the soft system methodology (SSM). This approach will guide the evolutionary process of analysing the information flows, defining the databases, knowledge encoding and

requirements for on-line control. Specifically, it is the objective to understand the soft-system activities of farmers and produce a model of the individual FMIS components, indicating where the FMIS will be required to assist/enable information flows. Subsequently this model should be transformed into a format that computer scientists can use as the basis for a more formal and implementation-based description of the proposed FMIS (using e.g. UML). Also, a further objective is to demonstrate how the applied SSM method can assist in the case of agriculture which has the special feature that the main actor (the farmer) is not an IT/computing specialist, giving the additional requirement that the resulting system model should be easily understood by the farmer, who may struggle to understand a formal systems model.

2. Materials and methods

The boundaries and scope of a system can be described in terms of users, where users are entities interfacing with the system (e.g. managers, software, databases). In order to analyse the complex and soft systems situations of how to develop an effective FMIS, the soft systems methodology (SSM) was used (Checkland and Scholes, 1999; Wilson, 2001). This approach involves identification of the scope of the system, identification of user requirements and conceptual modelling. It has been successfully used in many fields of

applications from the health service (e.g. Checkland and Scholes, 1999) to urban development (e.g. Kasimin and Yusoff, 1996) as well as military operations (Staker, 1999). The application of SSM in agriculture is covering a large number of agricultural domains such as the grain, sugar or beef industry (e.g. Macadam et al., 1990; Reid et al., 2000; Walker et al., 2001; Carberry et al., 2002; McCown 2002; Fountas et al., 2009).

2.1. Soft system methodology

Fig. 2 illustrates the process of SSM, basically comprising of the modelling of human activity systems, which can then be compared with the real-world and an idealised future situation in order to facilitate and structure further discussions and elaborations and changes. The outcome from this process is a model widely agreed by all actors (in this case, those involved in the farming system) and facilitators (in this case, the authors of this paper) to be relevant to the particular situation. SSM are divided into three main parts: exploring the current situation, building models and taking action (Checkland, 1988). As illustrated in Fig. 2, the approach is based on a comparison between real-world problem situations and conceptual models of proposed relevant system for dealing with these problems (Nidumolu et al., 2006). SSM consist of the analysis of the current status quo of the system including inherent problems and

activities, the definition of the system deriving the actual goal of the targeted system (“root definition”) and, finally, the proposed conceptual model for the development of the information system.

2.2. Empirical data and information

The system analysis and boundary specification was based on extracted data and information obtained from the pilot farms involved in the FutureFarm project. These farms were the WIMEX farm located in Germany, MESPOL MEDLOV farm in Czech Republic, Markinos farm in Greece and Bramstrup farm in Denmark.

The selected farms represent a wide range of regional characteristics in Europe as well as farm types. These ranges are necessary to allow sufficient coverage of relevant patterns of information demand and flow as well as their technical handling on the widely different European farms. The four pilot farms represent: (i) large conventional cash-crop farming systems as being typical for main-stream farming, having specific problems in managing huge information clusters, internally as well as externally (WIMEX farm), (ii) cash-crop farming systems under transformation conditions and growing in size with their specificity in a still very dynamic information and internal management environment and internal management (MESPOL MEDLOV), (iii) organic farming systems with special information management related to long-

term planning, ecology and consumer-relations (Bramstrup farm), and (iv) family farming systems with cash-crop production plus specialisation in a perennial crop and thus mixed information characteristics (Marinos farm).

2.3. Analysis phase

The analysis phase involved the identification of the system components applied to farm management and operations and the consideration of processes, conflicts and thoughts of an organisation as the basic outset for the design of a dedicated FMIS. The topics addressed with the four farmers were:

- What are the external actors the farm is dealing with (e.g. public entities, commercial companies, etc.)?
- What is working well in the farm (regarding particularly information management and exchange processes) and what is not working well and what would the farmer like to do about it?
- Regarding information processing, what would the farmer like to have to make their daily working life easier and to run the farm more effectively?

In order to achieve a better understanding of the current situation of the farm manager, the managers of the four pilot farms were asked to give their opinion about their specific situation which then formed the basis for developing a “rich picture” to describe soft and hard facts and the conflicts and problems that a farm manager currently faces, both from an external and as well as an internal point of view. The term ‘rich picture’ as used in SSM originates from recommendations made by Checkland and Scholes (1999), where this concept sums up the results of what the analyst undertakes and it is one of the first stages in the analysis of a problem situation. In this sense, a rich picture is an appreciation of the problem in the daily life of the farm managers today rather than a diagram as such, and the real utility of the picture is not in the picture itself, but in the process of constructing the picture. In this respect, the rich pictures were discussed with the four farm managers to ensure that their personal views were represented in the final version. By adhering to this approach, the analysis of the current situation includes the following steps:

- Record relationships, connections, influences, causes and effects among the entities in the domain being studied.
- Include also more subjective elements such as character and characteristics as well as points of view, prejudices, spirit and human nature.
- Draw up a rich picture as pictorial ‘summaries’ of the physical, conceptual and emotional aspects of the situation at a given time.

In order to be able to model the proposed FMIS, the requirements and surroundings of the system needs to be clearly outlined and defined. This definition is called the “root definition” and this concept plays a central role in the analysis and modelling as it defines the goal of the system and brings forth various perspectives on a system and the inherent assumptions (Bergvall-Kareborn et al., 2004). The root definition is devised in the form PQR. A system to do P, by means of Q to achieve R or “What to do (P), How to do it (Q), and Why do it (R)” (Checkland and Scholes, 1999). Special attention should be paid to the elements of CATWOE, a mnemonic word representing the terms Customers (C), Actors (A), Transformation process (T), World-view (W), Ownership (O) and Environmental constraints (E). The core of CATWOE is the T and the W, where the World-view depicts the world-view for which the system has meaning and the Transformation depicts functionality on the system level. Customers are the ones influenced by the transformation as they benefit and suffer from it; Actors are the ones that carry out

the system activity and the Ownership belongs to the ones with the power to initiate or terminate the activity system; and Environmental constraints represent elements which are taken as outside the system and imposed on the system. Checkland and Scholes (1999) argued that the CATWOE transformation is more to elaborate since it includes additional and related elements and when included, will lead to transformation in a more elaborate manner since it includes additional and related elements and will lead to enriched root definitions and hence, better models. Experience has shown that omitting any of the elements in the CATWOE definition will cause the analysis to suffer (Checkland and Scholes, 1999).

As every model should be evaluated for its performance, in the case of SSM this is attained by employing the 3Es: efficacy, efficiency and effectiveness, which encompass check of availability of system output, check on minimised resource input as well as a check on whether the system output supports the customer.

A conceptual model (Checkland, 1988) was formed to identify the main purposeful activities of the proposed FMIS through a set of logical actions implied by the root definition. The derivation of a conceptual model indicates the concept of the FMIS to be designed.

3. Results

The results from the study include the voiced concerns by the four farmers as the basis for developing the rich picture. Further, the rich picture forms the framework for defining the system in terms of derived situational elements of CATWOE.

3.1. The current situation

The important concerns and problems voiced by the farm manager include the time consuming tasks of monitoring field operations, manage the finances and application for subsidies which is further complicated by the lack of integrated soft and hardware to manage this work and the lack of coordination when such programs do exist. Also, the farmer voice a need for additional information and advanced technologies to manage monitoring and data acquisition on-line in the field. When looking at the external concerns, it mostly concerns the need for sustainable production of farm products, which is further pursued by regulations and the possibility to receive subsidies when more sustainable management practises are abided by. Table 2 lists the major concerns that the four farm managers expressed in terms of enhanced information handling at the farm level.

By using the voiced concerns of the farmers to frame the problem under study, the rich picture shown in Fig. 3 illustrates the current situation with its problems and conflicts. As it can be seen, the system structure is very complex and many external as well as internal entities and partners have an interest in the farming system.

In terms of information handling, the farmer needs to manage large amount of information in order to make economical and environmentally-sound decisions. Currently, this process is very labour intensive and for most parts is executed manually. The important concerns and problems communicated by the farm managers include the time required to monitor field operations; difficulties in managing the finances and applications for subsidies, which is further complicated by the lack of integrated software and hardware; and the lack of coordination when such programs do exist. The farm managers also expressed their need for additional information and advanced technologies to manage and monitor on-line data acquisition in the field. When looking at the external concerns, it is seen that this mostly refers to the need for sustainable production of farm products, which is further pursued by regulations and the possibility to receive subsidies when more sustainable management practises are abided by.

Table 2
The concern of farm managers at the pilot farms.

System components	Description	Problem, considerations
People	Central decision maker at the farm administration, district office, farmers' association, local affairs, customers (e.g. direct marketing), press and media, producers of agricultural equipment (direct or through distributor), supplier of operating materials (like diesel, fertiliser, pesticides, etc.), EU, the environment and relation with neighbours, etc.	<ul style="list-style-type: none"> - Often engulfed in routine tasks - No time to concentrate on strategic issues - Very complicated regulatory framework - Good communication with commercial partner - Positive experience with direct marketing - Communication with external entities not optimal - Low environmental impact - Limited pollution - Limited odour
Activities/processes	Tasks or tools capable of collecting data/information on activities and processes at the farm: the acquisition of auxiliary materials and the marketing of farm products, planning and control of farm employees, extension services, etc.	<ul style="list-style-type: none"> Data/information overload No cross-linking of information Needs information in an automated and Summarised fashion Lack of information on market Acquisition of auxiliary' Material confusing Lack of easy accessible information on employee performance, etc. Lack of user-friendly software tools

Fig. 3. The current situation with internal and external conflicts and problems. The drawing is based on general elaborations and answers to questions posed to farm managers and the point of view of external partners involved in the study. The dark clouds symbolise conflict or problems, whereas the thick bobbles represent wants or needs for the future system.

Fig. 4. The current situation seen from the farm manger's point of view and the farm activity system for production of crops (the dotted circle). The stippled line defines the farm system boundaries.

3.2. Definition of the system

To define the outline of the system a derived rich picture from Fig. 3 focussing on the farm manager and the subsequent everyday management problems were derived making the system easier to comprehend – see Fig. 4. This figure shows the perceived boundaries of the proposed system.

The central entities in the proposed system include the farm manager, the fields, the products and production input. The Ministry of Agriculture and the consumer as external components are included since the system is very much influenced by these entities. Based on the boundaries identified above, the system was defined and the derived situational elements of CATWOE are listed below.

3.2.1. CATWOE

Customers. The primary customer of the proposed information system is the farm manager. The secondary customers are national and/or regional administrations, certification bodies, retailers, etc., understood as entities setting up and imposing standards and other regulatory frameworks for the farm production, and benefitting from the improved crop production.

Actors. The actor is the one operating the information system, which in this case is the farm manager or other farm staff.

Transformation process. The transformation process involves the transformation of operational field data into manageable infor-

mation for regulatory purposes and decision making for crop production.

World-view. The World-view is the hypothesis that drives the information system development. In this case, the view is that operational data is easily acquired and can be used to improve management decision making throughout the production cycle, and that the same data may be used to demonstrate to external agencies the farm's compliance with standards.

Ownership. The farm manager is the owner in the way that he has everyday decision making responsibility, and decides whether the system is of use or not.

Environmental constraints. The constraints influencing the usability and performance of the information system includes the expectations of the regulators for readily-available information to audit compliance with the standards and regulations on the farm, as well as the reliability and structure of the information technology (communication devices, server, databases, etc.). Additionally, the form in which the requirements and expectations of the regulators are made available must be considered a constraint.

3.2.2. Root definition

The root definition of the purposeful activity handled, derived from the interviews with farmers, is: "a FMIS (operated on farm level) to support real-time management decision making and

Fig. 5. The conceptual model.

compliance to management standards, by means of automated acquiring and contextualising operation data and external parameters (e.g. regulations, best management practises (BMP's), market information, etc.) to form a foundation for decision making in order to improve the quality of decision making and reduce the time required".

3.2.3. The 3Es

In order to evaluate the proposed system upon implementation, the following indices are used:

Efficacy: Is the data collected and analysed?

Efficiency: How much effort is used for obtaining the data (input) and transforming it and is it all used?

Effectiveness: Does it improve decision making?

3.3. Conceptual model

A rich picture of the concept of the proposed FMIS is illustrated in Fig. 5 below. It can be seen that the system comprises a large number of sensors and other systems for data collection on the farm in the course of the crop production cycle. The automatically acquired data complement the monitoring of the operational activities. Furthermore, the structure of the FMIS should enable the interrelation with external systems (e.g. financial, market, administration, etc.).

Fig. 5 shows the processes in the conceptual model as derived from the definition of the system. It is depicted how the operational field data needs to be collected and transformed in an automated way. The filtering of information (external as well as internal field

operation data) is initiated by the farm manager according to the operational activity which is to be planned. This relates to issues such as ideas and advice, counselling, information flow from administration and regulations. depicted in the rich pictures. Based on this, an execution plan can be generated and sent to the executor (e.g. the equipment, staff or service provider that is to carry out the operation) and finally, a record of the executed operations will be prepared. In the rich picture, these planning activities are presented as managing field operations, performance monitoring, order manage, manage pay, etc. This reporting subsystem can furthermore be used in documentation of farm practice toward government, buyers or consumers.

Based on this conceptual model for the FMIS derived from SSM analysis, a more formal systems model is presented in Fig. 6 using UML notation.

The model divides the FMIS into four functional components: internal data collection, external information collection, plan generation and report generation. The data collection and processing is an automated monitoring system, whereas the report and plan subsystems are to be initiated by the farm manager. From this component-based model of the required system, the formal specification of the behaviour and interfaces of each component, based on the dependencies illustrated in Fig. 6 (dashed arrows), may be straightforwardly derived and used as the basis for implementations. Table 3 presents some possible implementations of the various components of the proposed FMIS.

The external repository contains information on standards, rules, all types of guidelines for farm activities etc., made available for the FMIS. This should not be understood as a monolithic database, but rather a distributed system such as may be imple-

Fig. 6. The concept of the FMIS to be developed.

mented through a form of Service Oriented Architecture (SOA) architecture, providing the necessary open standard interfaces and data transfer formats. The decision making and plan generation performed by the manager are influenced by a number of factors, such as experience, preferences, the availability of best management practises (BMP's), the social context surrounding the manager and chosen management strategy.

4. Discussion

The soft systems methodology (SSM) targets organisational business and process modelling and identifies unstructured problems as well as identifying non-obvious problem solutions in a holistic view. Specifically, the approach provides the possibility of more clearly capturing the change that is necessary for a cur-

Table 3 Possible implementations of the component-based model of the FMIS.

Components	Possible implementations
Farm activity monitoring	Sensor readings from process activities (e.g. fuel consumption, yield measurements, RFID, GPS)
Data acquisition	Capturing of the sensor data and possibly presentation to the user (e.g. tractor terminal, mobile terminal, individual implement displays)
Data transfer	Transfer of the acquired data from the point of creation to some database or processing unit (e.g. GSM, GPRS, WLAN wireless technologies)
Data processing	Processing unit aggregating and/or deriving targeted indicators (e.g. central database, web-server, application logic)
Internal repository	Database holding information on the "operations history" of the farm (e.g. local database on the farmer pc or central database, such as the personalised web-database Danish field database (DAAS, 2009))
Search internal information	Locate specific information in the internal repository (e.g. specific search application logic)
Documentation generation	Derivation of indicators to evaluate compliance with norms, standards, etc. (e.g. special designed tools for specifying realised application rates, realised yields, etc.)
Extract to audit	Extraction of specific information for auditing (e.g. using specialised tools to extract the required and contextualised information)
Automated validation	Comparison between documentation and planned activities (e.g. specific tool for automated comparison)
Search external information	Locate specific information in the external distributed repository (e.g. specific search application logic for locating adverse sorts of guidelines for farming activities)
Information filtration	Contextualisation and specification of the needed information for planning purposes (e.g. application software for sorting and transforming data/information into the right formats, etc.)
Operations plan generation	Decision making and plan generation for the farming processes and operations (e.g. specialised planning software modules listing predicted application rates, machinery input, labour input, etc. – for example AGROffice (2009))
Plan repository	Repository holding and listing the generated plans at specific times (e.g. a dedicated database)
Plan execution	Actual execution of the planned activities (e.g. invoking different control system – for example downloading task files (task specification) to the tractor controller (TC) for subsequently execution and control by the implement control unit (ECU))

Table 4
Perceived strengths and weaknesses of SSM and UML.

Modelling technique	Soft systems modelling	Unified modelling language
Strengths	Process-oriented methodology Multiple state, both existing and required systems Explicit identification of current problems and required changes Wide-ranging model Easily understood by lay persons	Solution-oriented methodology Hard model, may be directly used in implementations Easily understood by software engineers and experts Formal set of semantics and expressions
Weaknesses	Soft model, implementation design requires further hard modelling Lack of formal semantics, requires interpretation	Single state, either existing system or planned system Hard to understand for lay persons

rent system to transform into a proposed system that will fulfil the user requirements of tomorrow. In this way, the SSM becomes a way of interpreting the language of the farmer into a form suitable for the computer scientist. This is an advantage compared with more hard-systems approaches, where, for example, activity diagrams follows a more stringent way of analysing the problem under consideration (Jackson, 2001; Christis, 2005). The SSM capture the issue that information design is not solely about computing but as much about organisational processes and the context in which the designed information system will eventually have to function (Davies, 1989).

Further hard-systems approaches such as Core-Task Analysis have as a prerequisites that the system under consideration is from the start organised in a systematic way (Norros, 2004). The final implementation will require the more hard system requirements analysis but the soft system methodology in this case is seen as preceding the detailed requirements specification in terms of establishing the main components of the system including the system boundaries. Given that farmers report significant problems in using current agricultural information management systems, and particularly in transferring information between systems (e.g. Pederson et al., 2004; Kitchen et al., 2005; Reichardt and Juergens, 2009), and the move to web- and web-service based management systems (e.g. Murakami et al., 2007; Nash et al., 2009b; Nikkilä et al., 2010), a fundamental analysis of current processes and structures, and the problems identified with them, is needed to ensure that the new generation of systems better meet the needs of farmers in terms of functionality, interfaces and parties involved. The use of SSM allows such a fundamental analysis, incorporating the identification of required changes. The unstructured analysis enables the identification of existing constraints, and possible solutions, which may not be apparent using more structured methods (Checkland and Scholes, 1999).

Previous studies analysing information transfers in precision farming, and proposing new models for farm management information systems have tended to use formal, hard-systems analysis techniques. For example, Nash et al. (2007) used UML modelling to identify uses for geospatial web-services, developing a model from use-case analysis through to process modelling and implementation models. Table 4 compares such a hard modelling approach using UML to the SSM approach presented here. In summary, it can be stated that the SSM approach gives more flexibility and a better communication with farmers and other potential end users during the initial analysis phase, and allows the explicit identification of problems and desires for change. However, the informal models resulting from SSM are not in themselves sufficient as the basis for the implementation of new information systems – for this a formal hard-systems modelling approach such as UML is required in order to specify, first in an abstract and subsequently in a detailed technical form, the exact behaviour of different components of the system and their interfaces. The advantage of using SSM is the broader scope of the initial modelling phase, allowing all parties to be involved and to specify both the current and the required systems. The agreed SSM specification of the required system may then be used as the basis for the formal modelling.

It has to be noted that a system may be technical and economic feasible from a hard system perspective but still rejected from other reasons. Soft system issues are often related to personality acceptance and social feasibility. Therefore, issues such as ethics, honesty, good will and moral may have an impact on motivation, de-motivation or acceptance of an innovation/technology solution (Wilson, 1988).

5. Conclusions

As part of specifying and designing a new farm information management system (FMIS) for precision farming, a rich picture has been derived capturing the processes and concerns of the farmer in terms of information handling. The focus is on the farm manager and the subsequent everyday management problems with central entities in the proposed system including the farm manager, the fields, the products and production input. Based on the identified boundaries, the system was defined in terms of the derived customers, actors, transformation process, world-view, ownership and environmental constraints.

Based on this initial outline of the system, a conceptual model was derived from the definition of the system. The conceptual model for the FMIS is divided into four sections: internal data collection, external information collection, plan generation and report generation. The data collection and processing is an automated monitoring system, whereas the report and plan subsystems are to be initiated by the farm manager. The external repository contains information on standards, rules, all types of guidelines for farm activities etc., made available for the FMIS.

This research has shown the benefit of using dedicated system analysis methodologies as a preliminary step to the actual design of a novel farm management information system compared with other more rigid and activity oriented system analysis methods. It has been shown that use of SSM allows a fundamental analysis, incorporating the identification of required changes and most importantly, the unstructured analysis enables the identification of existing constraints, and possible solutions, which may not be apparent using more structured methods. The next step in the design process will involve detailing and specifying the information flows inherent in the proposed information system and using formal hard-systems modelling approaches such as UML to produce detailed specifications of each of the identified components.
